

Opening Narrative about "Japanese Animation Film Schema"

Name: Bak Ji Yong

Number: 2023314052

The topic initially considered for the domain was "film." However, this subject already had numerous existing schemas, and its scope proved excessively broad for an assignment constrained by limited time and resources. Consequently, it became necessary to narrow the topic. Reflecting personal interests, the focus was progressively refined. As a result, a domain was developed that could encompass both films and Japanese animation, two areas of interest.

Ultimately, this domain offered several advantages. First, familiarity with the subject facilitated the process of designing the schema. Second, genuine enjoyment of the topic made it possible to sustain interest and motivation throughout the assignment. Finally, because the topic had been sufficiently narrowed, it was less frequently emphasized in other schemata and represented the most practical choice given the available resources.

Japan Animation Film is defined according to the following criteria:

1. The work must have a runtime of at least 40 minutes (in other words, it must qualify as a film).
2. The work must be produced in Japan; in cases of international collaboration, Japan must be the primary contributor.
3. Japanese must be the principal language used in the film.

Based on the selected domain (Japan Animation Film), the intended users were identified. The target audience of the metadata consists of "casual film enthusiasts with little or no prior exposure to Japanese animated films." This decision was made for the following reasons.

First, because the concept of film is often semantically associated with live-action productions, some audiences may perceive animated films as unfamiliar or may even avoid them. This observation was derived both from the experiences of acquaintances and from actual film statistics, which indicate that live-action films generally attract larger audiences than animated films in Korea. Second, individuals who do not enjoy the film format itself are unlikely to have any interest in this domain. Therefore, a basic interest in films was assumed as a prerequisite.

At the same time, although the intended users were defined as described above, the data were designed to accommodate a broad range of information through extensive metadata descriptions and multiple access points, thereby addressing diverse information needs.

No major structural revisions occurred from the initial draft of the schema to its final version. Nevertheless, numerous changes were made in smaller details step by step. The area that underwent the greatest degree of modification involved translating example elements derived from external schemata into actual XSD implementations. Various direct and indirect challenges hindered the schema development process, including inconsistencies with the originally planned structure, misunderstandings regarding the external schema intended for import, limitations in expression, and significant constraints imposed by the act of importing external schemata. Consequently, solutions had to be sought for each of these issues.

The first strategy involved the use of lecture materials and W3Schools. Reviewing lecture materials and learning the fundamentals of XSD construction through W3Schools gradually improved expressive capability. However, these resources alone were insufficient to represent every intended concept. Therefore, AI was actively employed to inquire about appropriate structures for desired expressions and to verify whether personally constructed structures accurately conveyed their intended meanings.

The second strategy consisted of reexamining the external schemata. A comprehensive review of the schemata initially selected for use was conducted, with the aim of preserving their original meanings as faithfully as possible during the import process. Whereas the initial selection had been based primarily on external semantic considerations, this broader review made it possible to incorporate more detailed implementation strategies into the schema.

Finally, as mentioned above, assistance from AI was utilized throughout the process. Although preferences regarding AI use naturally vary among individuals, this assignment actively incorporated AI within the boundaries permitted by the instructor. Rather than asking simplistic questions such as requesting the AI to generate the schema directly, repeated cycles of questioning and searching were undertaken to understand and appropriately apply the results it suggested. This process repeatedly demonstrated AI's strengths as a learning partner, although a more detailed discussion of this point would diverge somewhat from the primary purpose of this assignment.

While most revisions concerned relatively minor details, several notable changes included the following:

1. The addition of a homemade element, "rating."
2. The introduction of additional constraints on the "description" element.
3. More extensive use of "xml" to restrict language usage.
4. The inclusion of necessary information through documentation and comments.
5. Connections to external standards in order to organize "Genre" in a more detailed and systematic manner.

The schema structure is relatively simple and straightforward, and the dictionary lists have been carefully organized. Therefore, substantial difficulty in understanding the overall structure is not anticipated. Nevertheless, the following considerations may facilitate understanding.

Because animated films do not feature actors appearing on screen in person, voice actors assume the corresponding characters. Accordingly, the inclusion of a voice actor component in the schema was considered essential.

Furthermore, because the visual composition of animated films relies on CG or drawing techniques rather than cinematographic filming, artistic style permeates the work as a whole. This characteristic explains the inclusion of the technique element within the schema.

Apart from these aspects, no particularly specialized knowledge is required for understanding the schema. However, because multiple schemata are referenced, comprehension is greatly aided by examining both the external files and the primary file (Japanese Animation Film schema file) simultaneously.
